

Dr. Federica Villa

#### **KEYBOARD**– Evaluation Board Components Overview

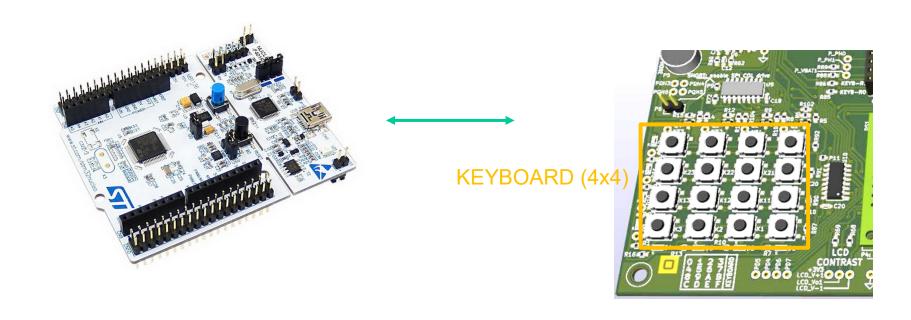

**KEYBOARD** 

STM32: KEYBOARD federica.villa@polimi.it 2 / 11

#### **KEYBOARD** – *PMDB16 details*

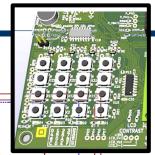

#### In our PMDB16 board:

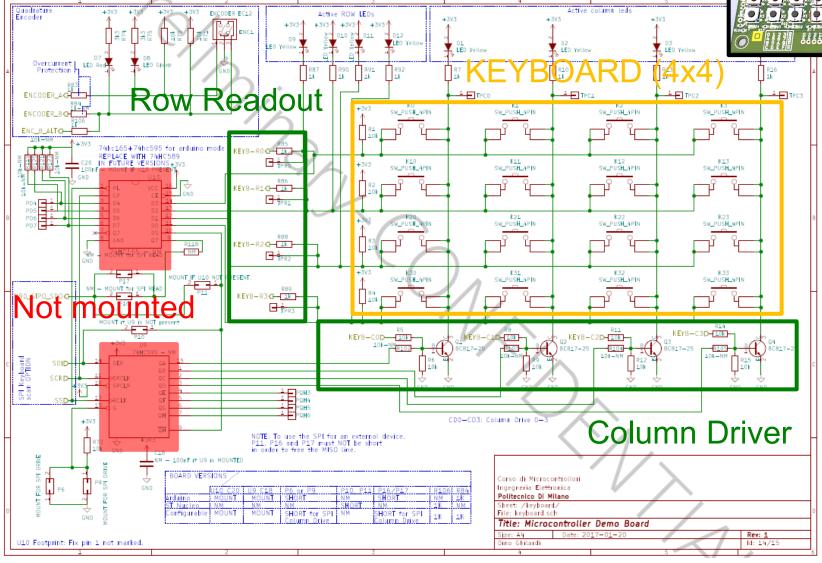

- U9 not mounted, instead we have P10
- U10 not mounted, instead we have P11

STM32: KEYBOARD federica.villa@polimi.it 3 / 11

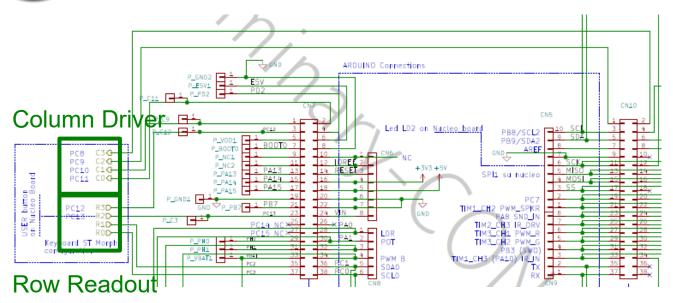

#### **KEYBOARD** – Schematic overview

#### **KEYBOARD** – Pinout configuration

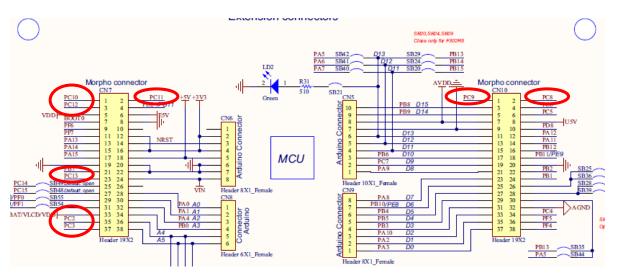

- PC13

- PC11

PC8 PC9 - PC10

**GPIO** output

federica.villa@polimi.it **STM32**: KEYBOARD 5 / 11

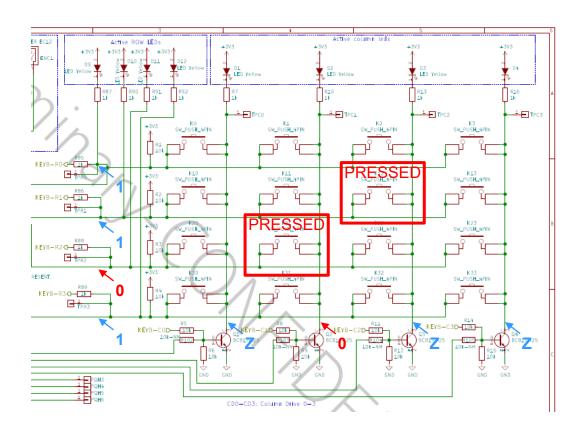

#### **KEYBOARD** – How to read a key

**Pull-up resistors** on the row lines

**Open collector** transistors on the column line pull it to ground or leave it floating

#### To read a key:

- Scan periodically across the keyboard by enabling one column at a time
- Read the 4 rows:
  - if a row is high (='1') then the key is NOT pressed
  - Else, the key IS pressed
- To debounce, wait for a minimum keypress duration before calidating the input

STM32: KEYBOARD federica.villa@polimi.it 6 / 11

## **Project 1a - Objective**

Objective

Scan each column and read the keyboard using polling

STM32: KEYBOARD federica.villa@polimi.it 7 / 11

#### **Project hints**

- Configure the 8 GPIOs required to scan the keyboard.
- Within your main loop, select one column at a time, wait for a certain amount of time, then read the status of the 4 rows. Scan through all 4 columns.

- For each pressed key, send the corresponding character to PC via UART. Do not repeat the key send if the key remain pressed at the following iterations. Send the code again if the key is released and pressed again.
- Compile and debug the code. (Suggestion: step through each column slowly and check the code operation)

STM32: KEYBOARD federica.villa@polimi.it 8 / 11

# **Project 1b - Objective**

Objective

Scan each column and read the keyboard using a timer interrupt

STM32: KEYBOARD federica.villa@polimi.it 9 / 11

#### **Project hints**

- Configure the 8 GPIOs required to scan the keyboard.
- Setup a timer to provide an interrupt every few ms. In the callback, acquire the status of the 4 rows and then enable a new column. Figure out a way to keep track of when each of the 16 keys is pressed and for how long.
- Within the loop(), if a key is pressed long enough, send the corresponding character to PC via UART. Do not repeat the key send if the key remain pressed. Send the code again if the key is released and pressed again.

Compile and debug the code. (Suggestion: step through each column slowly and check the code operation)

federica.villa@polimi.it **STM32**: KEYBOARD 10 / 11

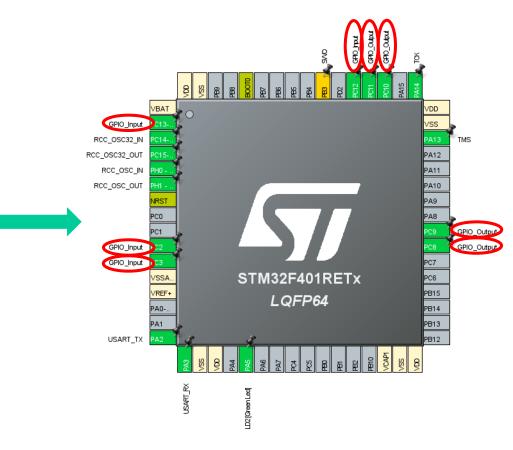

## Project 1 - Setting on CUBE pinout (1)

# Starting from a default model project

vss B1 [Blue PushButton] RCC OSC32 IN RCC OSC32 OUT RCC\_OSC\_IN RCC\_OSC\_OUT PA9 PA8 PC9 PC8 РСЗ PC7 STM32F401RETx VREF PB15 LQFP64 PB14 USART\_TX PB12

# Select the following GPIO\_input and GPIO\_output ports
